## PREFACE

THIS work owes its inception to a chance remark made to the author when, whilst serving with the United States armed forces in Europe, he paid brief visits to the Museum in July and December, 1945, for the purpose of examining type specimens in the Meyrick collection. Edward Meyrick had died in 1938, bequeathing his collection to the British Museum, where it arrived in May of the same year. It was hardly ready for critical examination when war broke out and it had to be sent out of London again for safety, for it was estimated to contain the type specimens of at least ten thousand species.

The richness of Meyrick's collections reflects the fact that for almost half a century the great bulk of all critical material, and much other as well, was referred to Meyrick almost as a matter of routine by Commonwealth microlepidopterists and by many others; a specimen identified by Meyrick was no longer a subject of inquiry in so far as its name was concerned, and for almost half a century Meyrick dominated this field. However, the use of morphological characters that Meyrick steadfastly refused to recognise began eventually to cast doubts on some of his conclusions, and it became a matter of importance that Meyrick's type specimens should be re-examined with the aid of the latest techniques. In 1945 there was in the Department nobody available to undertake this work. The advent of Mr. Gates Clarke, who was already a microlepidopterist of wide experience, was therefore most opportune, for it led to his being seconded by the United States Department of Agriculture for duty in the British Museum (Natural History) for a period of two and a half years. The scope of his work he has himself defined in the Introduction to this first volume, which, it is anticipated, will be followed by at least four others. The Trustees believe that these will provide the solutions of many taxonomic puzzles and they take this opportunity of expressing their deep sense of gratitude to the author, and to the United States authorities who so generously made his services available to them.

# INTRODUCTION

THE object of this work is to select, and designate where necessary, lectotypes of species of Microlepidoptera described by Edward Meyrick, and to establish the types when the species were described from uniques; to illustrate the wings and genitalia of the lectotypes and types and thus stabilise the nomenclature of the species examined at the British Museum (Natural History). As a secondary object a complete alphabetical list of all the species of Microlepidoptera described by Meyrick, with a citation to the original description of each, has been compiled and is published in this first volume.

This study has been undertaken as a joint project of the British Museum (Natural History), the Bureau of Entomology and Plant Quarantine, U.S. Department of Agriculture, and the Smithsonian Institution, Washington, D.C.

The Meyrick material in the British Museum consists of two parts; that placed in the Museum by Meyrick when he described species from Museum material, or specimens that found their way to the Museum in acquisitions, such as the Paravicini Collection; and that which was acquired when Meyrick's personal collection was given to the British Museum after his death.

No one appears to know when Meyrick decided to deposit his collection in the British Museum, but certainly it was not always his intention to do so. The following is a quotation from a letter addressed to Lord Walsingham.<sup>1</sup> “. . . I should like, in the interests of science generally, to supply you with types of as many species as possible, which might serve to illustrate my descriptions. It would afford me much more satisfaction to endeavour to form such a collection to be placed in your hands, than to allow my specimens to be placed in the British Museum, where they would be lost in the general confusion.” Later,<sup>2</sup> however, Meyrick leaves no doubt about the ultimate disposition of his valuable collection.

Meyrick's collection consists of about 100,000 specimens, containing by far the great bulk of his types, and was housed in well over two hundred double-sided store-boxes measuring 11 by 16 inches. On Plate 2 one side of a box of GELECHIIDAE is illustrated to show how Meyrick arranged his collection. The series begin in the upper left-hand corner of the lid of each box.

All the specimens are mounted on small pins, a large proportion of which have developed verdigris, causing damage to many specimens, some to the extent that they have fallen off the pins, while others have been split.

This vast collection was obtained from numerous sources all over the world, from institutions and students who sought Meyrick's help, from collectors, presumably paid from Meyrick's personal funds, and through his own efforts.

Meyrick spent the years 1877-1886 as a schoolmaster in New Zealand and Australia and obtained there great quantities of new species and genera. These specimens form the largest part of his collection from these regions, are exquisitely prepared and form the finest section of the collection. Most of the descriptions of the species from New

<sup>1</sup> Meyrick to Walsingham *in litt.*, Ramsbury, Hungerford, Wiltshire, 6.2.84.

<sup>2</sup> *Deuts. Ent. Zeit., Iris*, 52: 73, 1938.

Zealand occur in the *Transactions and Proceedings of the New Zealand Institute*, those from Australia being published in the *Proceedings of the Linnean Society of New South Wales*.

The chief contributors in the Asiatic region were Mr. E. E. Green, Government Entomologist of Ceylon, Mr. J. Pole, Mr. G. C. Alston, and Mr. G. B. de Mowbray of Maskeliya, Ceylon, Mr. W. Vaughan of Madulsima, and Mr. L. C. H. Young of Bombay. Between them they are responsible for almost the entire knowledge of the microlepidopterous fauna of Ceylon. Chief among the contributors from India was the late Fleet Paymaster T. Bainbrigg Fletcher, who spent more than a quarter of a century in that country. Much of his material was reared, his studies in this connection being supplemented by Meyrick's work on the taxonomy of the many species. A large quantity of material was described from the Khasi Hills, Assam, where it was collected by native collectors. The specimens from the Nilgiri Hills, North Coorg, were obtained by L. Newcome. Many others contributed to the knowledge of the fauna of the Indian region but their material was not so extensive. The great majority of the species from Ceylon and India were described in volumes 16 to 23 of the *Journal of the Bombay Natural History Society*.

The Chinese fauna, yet very imperfectly known, is represented mostly by material collected by Prince Aristide Caradja of Rumania and Dr. H. Höne of Bonn, Germany. Many of the types are in the Meyrick collection although some (according to information compiled by the late G. A. Bissett probably no less than 257 types) remained in the Caradja Collection now the property of the Muzeul de Istorie Naturală, Bucharest, Rumania. A considerable quantity of specimens was obtained by C. F. Baker and submitted to Meyrick by the late August Busck of the U.S. National Museum of Washington, D.C. The types of the species described by Meyrick from this last material were retained by him and all bear "AB" (August Busck) in the lower left corner of the pin-label.

Japanese and Formosan species were supplied by Professor S. Issiki and Professor T. Esaki, of Tokyo, and were nearly all reared.

The Chinese species supplied by Prince Caradja and by Dr. Höne were described in a separately published volume of the *Deutsches Entomologische Zeitschrift, Iris*, entitled "Materialien zu einer Microlepidopteren Fauna der Chinesischen Provinzen Kiangsu, Chekiang und Hunan, 1935"; and in the *Bulletin de la Section Scientifique* of the *Académie Roumaine*.

The descriptions of the Japanese and Formosan species will be found in *Exotic Microlepidoptera*. Much material was described from other Pacific areas, principally from Papua (Miss Cheesman), Pacific Islands (St. George Expedition 1924-5) and the Hawaiian Islands. The Papuan and Pacific Islands species, exclusive of those from the Hawaiian Islands, were described in the *Transactions of the Entomological Society of London*. The Hawaiian species were described in *Pacific Entomological Survey*, Pub. 7, Art. 28, 1934 and in *Exotic Microlepidoptera*, and most of the types are deposited in Hawaii.

For a knowledge of the African fauna we are indebted primarily to Dr. A. J. T. Janse of Pretoria and to C. J. Swierstra, whose early collections provided the initial impetus for the study of African Microlepidoptera. The types of the species from these early collections are distributed in the Transvaal Museum, Pretoria, the South African Museum at Cape Town and the Meyrick Collection. Most of the species were described

in the *Annals of the Transvaal Museum* and the *Annals of the South African Museum*. The descriptions of species described in later years, however, are to be found scattered throughout the several volumes of *Exotic Microlepidoptera*. Types of these last species are in the British Museum and the Belgian Congo Museum at Tervueren, Belgium.

The principal source of material from Madagascar was that collected by Dr. R. Jeannel and described in *Voyage de Ch. Alluaud et R. Jeannel en Afrique Oriental, 1911-12. Résultats scientifiques. Lepidoptera, II*, pp. 33-120 (Paris, A. Lhomme, 15 août 1920). The types from this expedition are in the Muséum National d'Histoire Naturelle in Paris. The descriptions of other species from Madagascar, from various sources, are to be found in *Exotic Microlepidoptera* and most of the types of these were retained by Meyrick.

The American fauna, as treated by Meyrick, consists chiefly of descriptions of species and genera from South America, although a considerable number of North American species were also described by him. The vast preponderance of South American, and some North American, material was supplied by H. S. Parish, formerly of Toronto, Ontario, Canada. The most important contribution by Parish concerns the great number of species submitted from Bartica and Mallali, British Guiana. Actually these, and the species contributed by Eugène Le Moult from French Guiana, constitute a large percentage of the known South American forms. Brazilian species and a few hundred from other South American localities comprise the known fauna from that region.

Seventy-six species from Southern Argentina and Chile were described in the *Anales del Museo Nacional de Historia Natural de Buenos Aires*, vol. 1, 1931, the remainder in *Exotic Microlepidoptera* and one or two other papers. All of the types, except some two hundred or more in the Deutschen Entomologischen Institut's collection, Berlin, Germany, about the same number in the Naturhistorisches Museum, Vienna, and a few scattered examples, were retained by Meyrick.

I have outlined briefly above the most important sources of Meyrick's material and have alluded to the disposition of the bulk of his types. It must be borne in mind, however, that the sources of supply were many and varied and types are scattered in numerous places, some of them unknown. We know also that certain types have disappeared and others have been destroyed, such as those of the Hamburgisches Zoologisches Museum und Institut, Hamburg, which were lost through bombing during World War II. Therefore, I have treated only the sources of Meyrick's material that provided large sections of his collection and have indicated the disposition of only the known types, not including the known repositories of small numbers of types; the latter are dealt with specifically in the catalogue of species.

Meyrick's descriptions of species and genera are contained in 420 books and papers of which the first was published in 1875 and the last, posthumously, in 1939.<sup>1</sup> It is not known how many species of Lepidoptera Meyrick described but I list in this volume 14,199 names of Microlepidoptera, exclusive of Pyralidoids (except the included PTEROPHORIDAE). Approximately 8000 of these were described in the first four and part of the fifth volumes of *Exotic Microlepidoptera*.

<sup>1</sup> For a complete bibliography, see Janse, A. J. T. and Fletcher, T. B., *The Moths of South Africa*, 4, part 1, xi-xxiv, 1942.

## CATALOGUES OF THE MEYRICK COLLECTION

AN integral and important part of the Meyrick Collection is the set of hand-written catalogues, compiled by Meyrick for the most part in ledgers measuring about eight inches by thirteen. In order to work with the insects of this collection, it is necessary to consult frequently many of these catalogues, others less frequently. In the following pages I deal with a few of the more important catalogues in detail, and all are listed below:

- No. 1. Index to genera and species, cross references to Nos. 6, 7 and 10. 302 pp.
- No. 2. Index to species of Pyrales, cross references to No. 13. (The pages are unnumbered.)
- No. 3. A list of South African Microlepidoptera numbered serially, with index. This consists of a large ledger with 687 species listed on the first 63 pages, with references to some, and localities for all. The index, appended at the back of the volume, consists of 4 pages.
- No. 4. A list of Asiatic Microlepidoptera with index. There are 1235 species listed on 113 pages. The index consists of 4 pages inserted at the end of the volume. References are given for most species and localities for all.
- No. 5. A list of Australian Pyrales and Microlepidoptera numbered serially. Indexed. This list consists of 3660 species on 333 pages (a few numbers are left open for additional species). The index of 15 pages is inserted at the end of the volume. References are given for nearly all species.
- No. 6. A catalogue of *Tineina*, *Hepialina* (genera and species). Pages numbered 1001-1754. Indexed in No. 1.
- No. 7. A catalogue of *Tineina* (genera and species). Pages numbered 1-698. This is indexed in No. 1 by page No. (Plate 4.)
- No. 8. A list of genera of PYRALIDAE (with descriptions). Indexed. Of the 225 double pages in this volume many are left blank for the addition of new genera. Under each genus, except synonyms, is a brief description of the characters. In the index, consisting of 6 pages, synonyms are indicated by a "+" to the left of the name.
- No. 9. An early list of Microlepidoptera taken by Meyrick and arranged after Staudinger and Wocke (*circa* 1875). 554 pp.
- No. 10. A catalogue of *Tortricina* (PHALONIIDAE) (genera and species). Pages numbered 2001-2478. Indexed in No. 1.
- No. 11. An alphabetical list of Pyralid Genera with type species and original references. 129 double pages. Type citations do not always conform to the International Rules of Zoological Nomenclature.
- No. 12. Food plants of Microlepidoptera arranged under genera with generic index. In this catalogue 316 of the 434 pages were in use, and 4 pages of index were inserted at the end of the ledger.
- No. 13. An index to the species of *Pyrales* arranged under genera with reference and distribution (incl. PTEROPHORIDAE). Index to genera. This catalogue

consists of 698 pages (arranged as are Nos. 6, 7 and 10), plus 10 pages of index to the genera, at the end of the volume.

- No. 14. Descriptions of *Tineid* genera of Microlepidoptera with index. There are 683 pages of brief characterisations of the genera and 19 pages of index (about 4250 names) at the end of the volume.
- No. 15. An alphabetical list of the genera of Microlepidoptera with type species and original references. 265 pp.
- No. 16. Descriptions of the genera of *Tortricina*, with index. Only a few of the 132 double pages are used. An index of 4 pages is inserted at the end of the ledger.
- No. 17. Notes on larvae and pupae. *Tort. Tin.* There are 159 pages, more or less filled with larval and pupal descriptions. A few drawings of wing venation will be found just past the middle of the ledger.
- No. 18. Copied descriptions of CHLIDANOTIDAE, CRAMBIDAE, PHYCIDAE [PHYCITIDAE], GALLERIIDAE, TORTRICIDAE, and PSYCHIDAE. Over 300 pages in minute hand-writing in German, French, Latin, etc., done with meticulous care. Several descriptions are augmented by sketches and coloured figures.
- No. 19 (1897-1916). No. 20 (missing). No. 21 (1924-30).
- No. 22 (1930-2). No. 23 (1933-6). No. 24 (1937-8).
- These catalogues contain the lists of the thousands of determinations made by Meyrick. A card (inserted in No. 21) from Meyrick's son, dated 10-v-40, alludes to the missing ledger: ". . . I am sorry to say that I can find no trace of the missing ledger. . . . It might be worth enquiring of Messrs. Quaritch, who took most of the entomological library. . . ."
- No. 24 (b). Extracts from various works. Copied descriptions of new species. Of the 332 pages only 141 were used.
- No. 25. Meyrick's Diary, 1872-90 (Captures). The captures are listed on 145 of the 470 pages, four columns to the page.
- No. 26. Copies of descriptions of GEOMETRIDAE and PYRALIDAE with Lederer's Key to Pyrales and his figures, Plates III-IX. The plates are copied in black and white.
- No. 27. Copied descriptions of genera and species of Microlepidoptera and PYRALIDAE, with structural drawings and coloured figures. 470 pp.
- No. 28. A list of Australian Microlepidoptera, including HEPIALIDAE, numbered serially and indexed. There are 1003 species listed, with a little over 4 pages devoted to the index.
- No. 29. A list of Australian Microlepidoptera (including PYRALIDAE), serially numbered from 1 to 2926. This list is not indexed. References to the original description, and localities, are given.
- No. 30. Descriptions of world genera, with keys and index. Consisting of 368 pages, 10 × 15½ inches, of which 346 were used. The index is missing. A few drawings of heads and palpi accompany the descriptions.
- No. 31. Species of *Tineina*, European. Contains copies of original descriptions, with a few coloured drawings by Meyrick. 270 pp., including "Index Methodicus" at the end of the volume.

Unnumbered. Sketches of *Tineid* venation.

(1) Small notebook containing Meyrick's notes on "A Revised Handbook of British Lepidoptera, 1928". 69 pp.

Two small notebooks containing pencilled notes and drawings of species in the British Museum and elsewhere on which Meyrick required further knowledge.

(2) pp. 59-158.

(3) pp. 159-202.

The contents of most of the catalogues are indicated by the title, but several need elucidation. Numbers 1 and 2 hold the key to the other catalogues. No. 1 contains the references to Nos. 6, 7 and 10; and No. 2 refers to No. 13. Since the system applied is the same in No. 1 and No. 2, and the arrangement of Nos. 6, 7 and 10 and 13 are identical, the explanations of two catalogues will suffice.

In No. 1 the pages up to p. 218 are devoted to an index of species; from p. 219 on, to the generic index. Plate 3 represents most of p. 63 of Catalogue No. 1. In this case, as with the genera (lower part of plate), the number following the name indicates the page on which the specific name will be found in No. 6, 7 or 10. Preceding some of the specific names will be seen "+", which denotes a synonym.

Plate 4 represents part of a page from Meyrick's genus "*Gelechia*" in No. 7. The vertical lines (a) in the extreme left-hand column show species actually represented by specimens in the Meyrick collection. The vertical lines (b) to the left of the locality represent species *known* to and recognised by Meyrick. Following each name is a reference to the original description but in many cases this reference is followed by others. Synonyms are entered after the name considered valid by Meyrick.

Names followed by "L46", "L90", etc. (c), will be found also in ledger No. 12 "Foodplants of Microlepidoptera arranged under genera . . ." where a notation of the host is recorded. The number following the "L" is the page number in ledger No. 12.

Names followed by "Sp.67", etc. (d), are recorded in ledger No. 27 "Copied Descriptions of Genera and Species of Microlepidoptera . . ." the number again referring to the page.

When a name is followed by "N155", etc. (e), this refers to a species in one of the small unnumbered notebooks indicated at the end of the above list of catalogues.

The names of New Zealand species are frequently followed by "Huds.128", etc., which refers to Hudson, G. V., *The Butterflies and Moths of New Zealand*, 1928, and the page in that work on which the particular species is mentioned.

In citing synonyms in ledgers Nos. 6, 7, 10 and 13, Meyrick usually deleted the name of the synonym and added it after the valid name. Unfortunately a considerable number of names, marked as synonyms in the specific indices, were not scratched out, resulting in some uncertainty as to what Meyrick did or did not consider a synonym.

Catalogues Nos. 11 and 15 are alphabetical lists of world genera of Microlepidoptera and Pyralidoids. The type species of each genus, according to Meyrick's concept, is cited. These type citations are not always in accordance with the International Rules of Zoological Nomenclature and are, therefore, incorrect in many cases.

A PAGE FROM MEYRICK'S CATALOGUE OF TINEINA (see page 6)

## LABELS AND LABELLING

TEXT figure 1 on p. 8 illustrates some of Meyrick's labels and also some of those that I have used in my work on the specimens in his collection.

Meyrick's labels are of two types: (1) printed and (2), handwritten. The first type was used for localities in Ceylon, Assam, North and South America, Africa, etc., from which so many specimens were acquired as to justify the printing of large quantities of labels. The second type was used for localities from which material was less frequently obtained and generally consisted of few specimens. All labels were simple and small with only the bare essentials, and frequently not those, on them. It was customary for Meyrick, upon receipt of labelled specimens which he intended to retain, to remove the original labels and write new ones in his own cramped style, to conserve space. These labels were designed to convey information to Meyrick but were made without reference to future understanding and, in many cases, it is possible to understand what was meant only by the most careful analysis of his personal records. It is, therefore, necessary to discuss certain labels to elucidate their meanings.

Almost without exception labels bearing rearing information were removed and destroyed. Such information was entered in Meyrick's personal catalogues when he considered such data of sufficient importance.

The labels to which I refer in text figure 1 are indicated by letters:

(a) "St. Jean, R. Maroni, Fr. Guiana. Le M. 7.15." This label is used for a vast quantity of material supplied by the dealer; Eugène Le Moutt of Paris. Le Moutt's name is mentioned only twice<sup>1</sup> in connection with the hundreds of descriptions of his material. Usually Meyrick labelled only one or two specimens "St. Jean" and the remainder of the series without that specific locality.

(b) "Bartica, Brit. Guiana. Parish. 1.13." This is the type of label used for specimens from South America supplied by H. S. Parish. Although most of the specimens bearing Parish's name were collected by him it appears that much of the material from Pará, Brazil, was actually obtained by the Rev. Miles Moss but was sent to Meyrick through Parish.

(c) "Brenster Co. Texas" was used for all material collected at "Alpine, Brewster County, Texas." As far as I know no correction of "Brenster" was ever made by Meyrick although Alpine, Texas, is a well known collecting locality, there being much material from this locality in the U.S. National Museum as well as other collections. Meyrick, without exception, published "Alpine, Texas" for his specimens.

(d) "Khasi Hills, Assam. 10.1906." Specimens bearing this label were almost invariably recorded by Meyrick from "Khasis". Just why this variation of "Khasi Hills" was used in Meyrick's publications is not clear but appears to be a personal peculiarity of the author. There is no indication from whom the specimens were obtained.

(e) "Dibidi, N. Coorg. LN. 3.4.10." and (f) "Dibidi, N. Coorg, Newcome. 12.5.07" are variations of the same thing. With few exceptions moths from this locality were recorded from "N. Coorg" or "Coorg" with rarely a reference to the specific locality.

<sup>1</sup> *Exotic Microlepidoptera*, 1: 45, 1915; 1.c. p. 435, 1915.

(g) "Nilgiri Hills, S. India. HLA. 6000'. 5.07." There are several variations in the labels for this locality. Almost always the published locality reads "Nilgiris".

(h) "Pusa, Bengal. TBF. bred. 15.7.15" and (i) "Pusa, Bihar, TBF. bred. 6.21" represent the same locality. A third variation reads, "Pusa, India." "TBF." are the initials of the eminent authority on Indian Microlepidoptera, the late T. Bainbrigge Fletcher of Stroud, Gloucester, England. Specimens supplied by Fletcher were, with few exceptions, reared. The only indication of this given on the labels is "bred". In every case the entire rearing data were removed and such notes as Meyrick considered necessary were entered in his catalogue of reared species. (Cat. No. 12.)

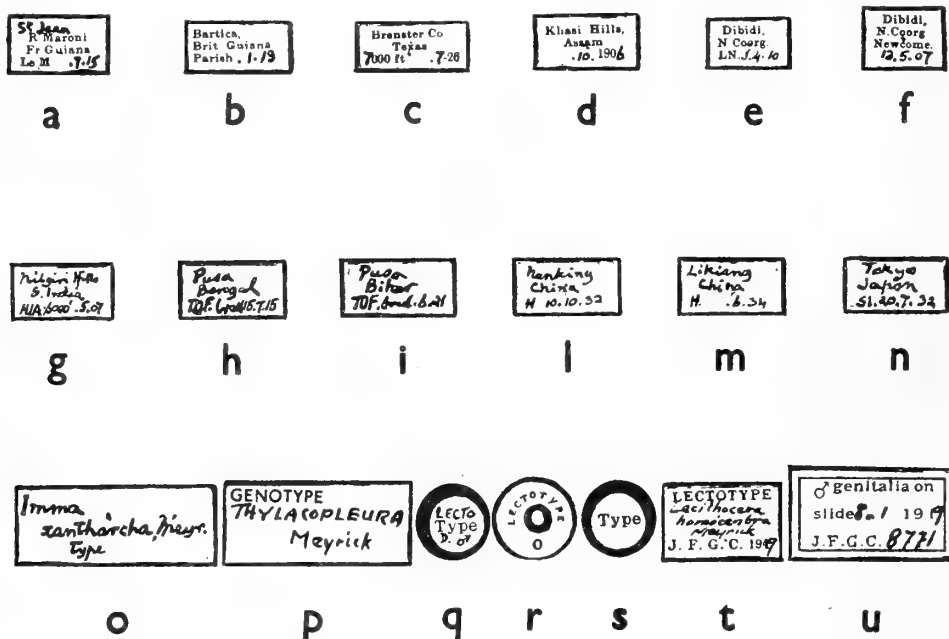

FIG. 1

(l) "Nanking, China. H. 10.10.32." All specimens collected by Dr. H. Höne at Nanking but recorded from "Lungtan" bear this label.

(m) The species described by Meyrick in "Materialen zu einer Microlepidopteren Fauna der Chinesischen Provinzen Kiangsu, Chekiang und Hunan", recorded from "Yul. . . ." all bear the label "Likiang, China".

(n) "Tokyo, Japan SI. 20.7.32." This label is representative of the kind used by Meyrick for moths collected in Japan and Formosa and submitted by Professor S. Issiki.

Another label, not illustrated, should be mentioned here. A substantial quantity of moths collected at "Toowong, Queensland, Australia" by Dodd, described by Meyrick from Thomas de Grey, Lord Walsingham's collection, were recorded from "Brisbane". In fact every type I have seen recorded from Brisbane is labelled "Toowong".

(o) This is an example of a rare Meyrick "type" label. Such labels are found on certain species of *Imma*, *Acrolophus*, some species of *Stenoma* in the U.S. National

Museum, and a comparatively few others. Meyrick's almost fanatical opposition to the labelling of types accounts for the scarcity of such specimens.

(p) "Genotype *Crocogma* Meyrick." I have attached this type of red label to all specimens that typify the type species of genera.

(q) This is the kind of label used by Diakonoff for certain types of Indo-Malayan TORTRICIDAE and CARPOSINIDAE. Reference to the lectotypes selected by him is made in the appropriate place in my work.

(r) The label shown here is the kind used by me in conjunction with that shown in figure "t". This is the "recognition label" and consists of a white disc with a central red ring with "LECTOTYPE" printed in black. "t" shows an example of the "name label", the name being written in my hand with the dates from 1947 to 1949. My initials appear at the bottom of the label.

(s) This tag is used in cases in which species were described from unique specimens, and consists of a red-ringed white disc with "TYPE" printed in black in the centre.

(u) To all specimens from which I have made a preparation of the genitalia I have attached such a label. In each case the sex is indicated together with the date of the preparation and the slide number. On each slide will be found a corresponding number and date, sex and a duplication of the pin-label data so that no confusion can possibly arise.

One other label, not illustrated, should be mentioned. Specimens from Nanking, China, described in "Materialien zu einer Microlepidopteren Fauna . . . etc." are recorded from "Lungtan".

When labelling a series of specimens, Meyrick had the peculiarity of frequently dating only one specimen in the series. This leads to some confusion but, generally, it is possible to distinguish original specimens from those, if any, added to the series subsequently.

Throughout the sixty-four years of the publication of this enormous number of species and genera, Meyrick seldom marked or designated a type. His contention, borne out in correspondence, was that a type specimen was of no value but that the *description* was the important factor. He had absolute confidence in the accuracy and completeness of his descriptions and resented any suggestion to the contrary. In this connection I quote from a letter to Busck,<sup>1</sup> ". . . I submit that your two specimens (sexes) suggested to be = *urosema* and *absoluta* Meyr. are not in the least like my descriptions of either of those species, which are carefully described, and have abundance of points for recognition. In particular, my *urosema* (which is a ♂ as stated) really has a 'strong black mark' as described on anal segment, . . ." <sup>2</sup> In another letter<sup>3</sup> concerning the identity of two Oecophorids, in which case Meyrick was correct, he wrote. "I am much obliged for the specimens of *Machimia huachucella* Busck, which is a true *Machimia*, but in supposing it identical with my *Cryptolechia diligenda* you are paying small compliment to my accuracy of description; they have hardly a character in common. Structurally the pointed forewings, sinuate termen, and terminal ending of vein 7, and in colour-characters the absence of markings on palpi, and whitish hindwings (all correctly set forth in my description, which is complete), as

<sup>1</sup> Meyrick to Busck: Thornhanger, Marlborough, 21.9.32.

<sup>2</sup> Busck stated that Meyrick's *urosema* was a female, which it proved to be, when I dissected the type.

<sup>3</sup> Meyrick to Busck: Thornhanger, Marlborough, 16.2.29.

well as the indication of the stigmata, show clearly that it is entirely distinct. If I had not been certain (from the neuration, without the ♂) that it was a *Cryptolechia*, I should not have described it."

A short excerpt, from another amusing letter, is worth quoting. This resulted from an exchange of opinions emerging from observations on a species with venational variations which Meyrick never admitted. I quote:<sup>1</sup> "I am simply amazed that you should venture to state positively that the wing of *agyrtodes* Meyr. which I sent you for study belonged to some other insect! Why did you not further display your knowledge by stating what insect it was? It was as I stated it to be, and was taken at random from a number of unset examples of the species, of which I could not examine the neuration until I had removed the wing. I will add that I believe the hindwing sent could not be attributed to any other described North American species. Also, it agrees with my description, which you alleged to be wrong. Do you suppose that I first wrote a wrong description, and afterwards manufactured a hindwing to fit it?"

<sup>1</sup> Meyrick to Busck: Thornhanger, Marlborough, 21.1.28.

## ARRANGEMENT AND SCOPE OF THE WORK

My arrangement of families, genera and species is not systematic. The families dealt with in each volume are grouped to make the volumes approximately the same size. In Volume II I have placed together the STENOMIDAE, XYLORYCTIDAE and COPROMORPHIDAE. This combines nearly related families, but this is purely a matter of convenience. Volume III will contain the TORTRICIDAE, PHALONIIDAE and OLETHREUTIDAE and probably the CARPOSINIDAE and CHLIDANOTIDAE; Volumes IV and V will deal with the GELECHIIDAE, OECOPHORIDAE, BLASTOBASIDAE and COSMOPTERYGIDAE and perhaps one or two small groups; Volume VI will contain such families as the HYPONOMEUTIDAE, GLYPHIPTERYGIDAE, TINEIDAE and ACROLOPHIDAE. This arrangement is at present tentative but is essentially that which will be followed. The genera and species included in each family are, with few exceptions, in accordance with Meyrick's concepts. But the species grouped under the genera are in line with relationships based on genitalic studies, combined with other characters, in so far as it has been possible to make proper generic assignments without proposing new generic names.

Under each family the genera are arranged alphabetically, whether synonyms or not, and the included species are also listed alphabetically under the generic headings. Synonyms are listed in their proper alphabetic positions and cross-indexed to the valid names. Generic synonyms, although appearing independently, are cited.

Each species is headed by its valid name. This is followed by a reference to the pertinent illustrations giving plate and figure numbers. Next is a reference to the original description citing the combination of generic and trivial names as they appeared when the species was described. Following this I present a brief extract from the original description to show sex, size and source of the material and, occasionally, Meyrick's remark indicating his belief as to the species relationships. This is done to establish beyond doubt that the original specimen or series was examined. I then denote the specimen selected as the "LECTOTYPE" or "TYPE". *All such references are to be considered type and lectotype designations unless otherwise specified.*<sup>1</sup> Following the above designations is the number (in parentheses) of the genitalic preparation which, in the case of the types of the genera, includes the right wings. The numbers run from 4400 to approximately 9600 and all slides are in the British Museum (Natural History). Under "Labels and labelling" I have discussed the pertinent labels associated with the type and lectotype designations and those associated with the slides of the genitalia. After the above designations an explanation of figures is given.

Where synonyms have been cited and figured I have given the synonymy under the references and then have indicated by the inclusion of the trivial names in brackets (example: [*accurata*] . . . [*perjura*]) that part of the text referable to the particular species.

<sup>1</sup> Wherever I have indicated that the type or lectotype has been selected by Diakonoff the reference is to, Diakonoff, A., "The type specimens of certain Oriental EUCOSMIDAE and CARPOSINIDAE", *Bulletin of the British Museum (Natural History) Entomology*, 1, No. 4: 275-300, 1950. (illus.)

In the second and succeeding volumes it will be noted that there are hundreds of generic transfers. Even so there is a considerable residue of species which have been left in the genera in which Meyrick placed them. Obviously a complete revision of the Microlepidoptera will require study of the types of other authors, and that is far beyond the scope of this work, so transfers have been made only in cases in which clear-cut genera already exist and the changes were mandatory.

FOLLOWING is a list of the families studied and the geographical areas from which the material came. It will be noted that the entire New Zealand and almost the entire Australian faunas are omitted.

STENOMIDAE	American family with one representative from Africa (acc. Meyrick).
XYLORYCTIDAE	Asiatic and African with two Australian species.
GELECHIIDAE	American, Asiatic and African with a few Australian species.
BLASTOBASIDAE	American and a few African species.
OECOPHORIDAE	American, Asiatic, some African and a few Australian species.
METACHANDIDAE	Asiatic and African.
ETHMIIDAE	American, Asiatic, African.
HYPONOMEUTIDAE	American, Asiatic and a few African species.
TINEIDAE	American, African (few).
STREPSIMANIDAE	Asiatic.
CHLIDANOTIDAE	Asiatic.
TORTRICIDAE	American, Asiatic, African; also a few species from Australia described from Walsingham material.
OLETHREUTIDAE	American, Asiatic, African.
CARPOSINIDAE	American, Asiatic, African.
COPROMORPHIDAE	American, Asiatic, African.
GLYPHIPTERYGIDAE	American, Asiatic, African.
ACROLOPHIDAE	American family.
PHALONIIDAE	American, Asiatic, African.
SCYTHRIDIDAE	American.
SCAEOSOPHIDAE	African family.
COSMOPTERYGIDAE	Those species which I have transferred from other families.
PHYSOPTILIDAE	Asiatic family.

Time did not permit the study of several families from the geographical areas listed, but an attempt was made to include all the species of a given family from the entire world exclusive of New Zealand and Australia.

## CLASSIFICATION

MEYRICK'S classification<sup>1</sup> is based primarily on the venation of the wings of Lepidoptera supplemented by such other characters<sup>2</sup> as he considered important. He even went so far as to lay down principles<sup>3</sup> of classification based solely on venational characters and ridiculed the value of other structural features, particularly those of the genitalia.

At the outset Meyrick began with a false premise and as late as 1928<sup>4</sup> he made the following statement: "In my classification the standard aimed at is an average of about 10 species to the genus and 50 genera to the family in the world fauna; which corresponds pretty nearly to the numbers found in the genera and natural orders adopted by botanists for flowering plants, whose history is bound up with that of the Lepidoptera. Some monotypic genera are of course necessary; the largest existing genus is *Stenoma*, which contains at present over 600 species. . . ."(!)

This was an attempt by Meyrick to employ a purely artificial hypothesis, based on a mathematical formula, to provide a convenient system to which he could fit his classification and one not based on natural phenomena and evolutionary development of the insects he proposed to study.

As will be pointed out in the following pages his "genus" *Stenoma* is one of the largest conglomerations of unrelated species ever brought under one name in the Lepidoptera.

Let us go a step further regarding his attitude toward the distinction of genera:<sup>5</sup> "(2) As to distinction of *Platyedra* and *Pectinophora* from one another, as genera, I should be glad if I could make it clear to you, *not* because of any different value set on genitalic structure, but on broad principles of the formation of genera. You wish to separate them on account of differences; I wish to unite them on account of resemblances. You will find on examination of my work that I always do so; I cannot give a better instance than that of *Depressaria*, where you and Walsingham and Durrant make two genera, whereas I make one, the difference of course being in neuration there. Similarly you make three genera of *Cerostoma*, while I make one. Look at Walsingham's and Durrant's splitting of *Acrolophus*, where I have consistently maintained one genus. You have plenty of supporters; every beginner and every specialist (i.e., everyone of narrow views) is on your side. That ought to show you that you are wrong. My views are wider, and I know I am right. Your views are founded on opinion, and you are anxious others should adopt them, because then you would feel you were right; mine are founded on reason, and I like others to think differently because it is more creditable to me; there is no credit in seeing only what everyone else sees."

His almost fanatical reliance on venation as a means of classification, although admitting considerable variation, coupled with an equally determined refusal to consider the genitalic organs as a means of classification not only of species but also of

<sup>1</sup> Meyrick, E., *Proc. Linnean Soc. N.S. Wales*, 5: 205, 1880.

<sup>2</sup> Meyrick, E., *Trans. Ent. Soc. London*, 1883, pp. 119-31.

<sup>3</sup> Meyrick, E., *Ent. Mon. Mag.*, 25: 175-8, 1889.

<sup>4</sup> Meyrick, E., *A Revised Handbook of British Lepidoptera*, p. 13, 1928.

<sup>5</sup> Meyrick, E., *in litt.*, to August Busck, Marlborough, Wilts., England, 14.12.27.

higher categories, led Meyrick astray in many cases. In this connection he stated,<sup>1</sup> "Thus colour and outline, the hairs of the larvae, and the genital organs of the imagos are likely to be of slight importance in the definition of groups; whilst neuration occupies a high position, except when directly influenced by an alteration in form of wing, which is seldom the case."

Although Meyrick disdained the use of genitalia in classification he condescended to mention them on several occasions<sup>2</sup> but then he gave only a superficial treatment of a few features which could be seen by denuding the uncus and ends of the harpes, and he never gave an illustration of one.

Regarding genera he says further,<sup>3</sup> "Genera which (according to Durrant) would be identical 'under a lens' but distinct 'under a microscope', are too fine for me. As one cannot convert all one's specimens into microscope slides. . . ."

This persistent refusal to examine the genitalia, in conjunction with other structures, not only led Meyrick into error in delimiting families and genera but accounted in large part for his misdetermination of the sexes of many of his species.

It will be noted throughout this work that I have pointed out numerous errors in the determination of the sex or sexes of the specimens before Meyrick when he described certain of his species. These errors are attributable to several causes: (1), Meyrick's inability to discover the sex of his specimens because of his use of nothing stronger than a small hand lens and his reliance on characters of the antenna, frenulum, etc., rather than genitalia; (2), probable *lapsi* in particular cases and, (3), misprints on the part of the compositor.

It is impossible to determine the causes of most of these errors but there are a few cases in which we can draw certain conclusions. In the description of *Gelechia sarcochlora*<sup>4</sup> the specimens were recorded as "♂" and all of them are "♀". It seems likely, in this case at least, since the ovipositors are clearly visible on all specimens, that this is a printer's error but we may suspect that Meyrick ignored the ovipositor and relied on the frenulum or antenna. Dissection would have removed any doubt.

To cite another example: *Ethmia acontias*<sup>5</sup> was described from eight specimens and the sex was recorded as "♂". Not only dissection, but an examination of the ovipositors of the specimens disclosed their sex to be ♀. Meyrick later discovered his error and corrected it<sup>6</sup> attributing the sexual designation to a misprint. These are only two of many examples which serve to illustrate the errors, from various causes, in the recording of sexes in Meyrick's work. A third is cited on an earlier page (*urosema*) and many others are disclosed in their proper places. I use the above examples to support my contention that closer examination and dissection could have eliminated many mistakes, and that the specimens I have examined are the actual types and not replacements.

But let us return to the matter of venation and examine specific cases. Meyrick<sup>7</sup> proposed the generic name *Baeonoma* (Stenomidae) for *mastodes*, which he cited as type, and four other species. He characterised the venation of the genus as follows: ". . . Forewings with 1b furcate, 2-5 approximated, 7 to termen, seldom 7 and 8 (*leucodelta*) or 8 and 9 (*holarga*) stalked, 11 from middle. Hindwings 1 or over 1,

<sup>2</sup> *Exotic Microlepidoptera*, 3: 164, 1925; *Trans. Ent. Soc. London*, 1913, pp. 192-9, 1913; *Trans. Ent. Soc. London*, 76: 521, 1929.

<sup>3</sup> Meyrick, E., *in litt.*, to August Busck: Thornhanger, 18.1.15.

<sup>4</sup> *Exotic Microlepidoptera*, 3: 491, 1929.

<sup>5</sup> *Journ. Bombay Nat. Hist. Soc.*, 17: 409, 1906.

<sup>6</sup> *Exotic Microlepidoptera*, 4: 603, 1935.

<sup>7</sup> *Exotic Microlepidoptera*, 1: 507, 1916.

trapezoidal-ovate, cilia  $\frac{2}{8}$  to  $\frac{3}{4}$ ; 3 and 4 connate, 5 somewhat approximated, 6 and 7 stalked."

With the above characterisation in mind, and also Meyrick's remarks on venation under *Stenomoma neastra*, let us examine the characters of the other species placed in *Baeonoma*.

*B. euphanes*: This species has veins 2 and 3 stalked in the forewing, all others separate. The venation of the hindwing is essentially the same as that of *mastodes*.

*B. helotypha*: The same venation as that found in *mastodes*.

*B. holarga*: The forewing has 2 and 3 stalked, 8 and 9 stalked, and 10 approximate to 9 at base. The hindwing is essentially the same as that of *mastodes*.

*B. infamis*: Veins 2, 3 and 4 are approximate and 7 and 8 are connate in the forewing. In the hindwing 3 and 4 are connate and 5 is approximate to 4.

*B. leucodelta*: Veins 2 and 3 are stalked; 7 and 8 are stalked in the forewing. The hindwing is that of *mastodes*.

*B. orthozona*: Forewing with veins 2 and 5 equidistant from 3 and 4 respectively; 3 and 4 approximate; 7, 8 and 9 approximate and equidistant. Hindwing with 3 and 4 short-stalked.

*B. suavis*: Forewing with 2 and 3 approximate toward base; 4 closely approximate to 3; 7 and 8 short-stalked and closely approximate to 9. In the hindwing 3 and 4 are short-stalked with 5 approximate.

By making a comparison of the details of venation enumerated above, with the figure of the venation of *mastodes* (Vol. II, pl. 71, fig. 1a), the differences are immediately apparent. *B. helotypha* and *B. mastodes* are congeneric as borne out not only by venational characters but also by the genitalia. With these two species I associate *favillata* which I have transferred from *Stenomoma*. Meyrick was correct in associating *leucodelta* with *euphanes* but wrong in placing them with *mastodes* and its congeners. They (*leucodelta* and *euphanes*) appear more closely related to some of the Old World XYLORYCTIDAE. *B. orthozona* differs from all the rest and its position is not clear. The two remaining species, *holarga* and *suavis*, are generically distinct from *mastodes*, *helotypha* and *favillata* and will require new genera unless they can be properly assigned to genera in the Old World XYLORYCTIDAE. I wish to point out here that the proper interpretation of the venational characters could easily have been reached with a closer observation of pattern, habitus and genitalic features.

Above I have pointed out the inadequacies of Meyrick's observations and the shortcomings of his too heavy reliance on venational characters. Meyrick himself would have admitted the close relationship of *mastodes*, *favillata* and *helotypha* had the characters of the genitalia, in combination with other features, been brought to his attention. The association of the other species, with the possible exception of *infamis*, is unnatural as demonstrated by pattern, venation and genitalia and their eventual reassignment is mandatory.

Meyrick's genera *Aphanoxena* (synonym of *Antaeotricha*), *Cerconota*, *Chlamydastis* (= *Ptilogenes*), *Eumiturga*, *Mysaromima*, *Orphnolechia*, *Paraspastis*, *Prasolithites* (synonym of *Antaeotricha*), *Psephomeres* form a related group within the family STENOMIDAE characterised by forked scales in the male genitalia (except perhaps in *Mysaromima* the male genitalia of which are not known) and a variously shaped, dentate, sclerotised plate for a signum in the females.

I have already discussed *Baeonoma* which, in the strict sense (*mastodes*, *helotypha* and *favillata*) is more closely allied to the Old World XYLORYCTIDAE than it is to the true Stenomids. *Dinotropa* is referable to the OECOPHORIDAE; *Hyalopseustis*, *Lychnocrates*, *Petasanthes*, *Rhodanasa*, *Thioscelis*, and *Timocratica* have Xyloryctid affinities and are peculiar to the New World Tropics.

The two closely related genera, *Neophylarcha* and *Rhopaloesetia*, assigned to the COPROMORPHIDAE, certainly do not belong there and stand alone in the unique development of the frenulum which in the male terminates in a lamella; in the female at least one bristle terminates in a lamella. (See: Vol. II, pl. 259, fig. 1a and pl. 263, fig. 1a.) These two probably represent members of a distinct family. *Cathelotis* appears to be a higher development of *Phycomorpha* and the latter closely related to *Ordrupia*. *Cathelotis*, then, if a true Copromorphid, which I doubt, should be related to the Old World genera *Copromorpha*, *Chersomorpha*, *Osidryas* and *Aegidomorpha* through *Phycomorpha* and *Ordrupia* or common ancestor. For the time being I am treating all of these genera under the family heading COPROMORPHIDAE.

The genus *Petalothyrsa*, assigned by Meyrick to the EPERMENIIDAE, belongs to the STENOMIDAE to which family I now assign it.

The genus *Stenoma*, as conceived by Meyrick, was a huge, unwieldy mass of more or less related species containing many forms with nearer relatives in other genera than those with which Meyrick associated them.

Of the genus *Stenoma* Meyrick wrote,<sup>1</sup> under the description of *Stenoma neastra*, "This would be referable to *Orphnolechia* Meyr. [which is correct!], but I am not able to maintain that genus, since insistence on the structural distinction separates closely allied species, and groups together others which are not allied. In the aggregate of species grouped under *Stenoma* the stalking of veins 2 and 3, or 2-4, or the anastomosing or confluence of 2 and 1c (a frequent character which has been generally overlooked) in the forewings, or the stalking of veins 6 and 7, or 8 and 9, or 10 and 11 of the forewings, or the stalking of veins 3 and 4 of hindwings, are all specific characters only, and not always constant even as such, recurring in unrelated groups of the genus, and disguising natural affinity instead of expressing it. This will be seen by inspection of the following descriptions of species, which are grouped according to approximate natural affinity, and these points of structure noted. Hence I consider Walsingham's genera *Aedemoses*, *Catarata*, *Athleta*, *Zetesima*, *Menestomorpha* and *Mothonica* as all untenable and to be suppressed."

Had Meyrick examined the genitalic structures of his species it would have been clear to him that, although his observations on the venational characters were in part true, they were not entirely so and the proper interpretation of these characters could have been established by the genitalia.

The genus *Stenoma* is based on a single female, *Stenoma litura* Zeller, now in the British Museum (Natural History), which is unlike any of the 600 or so species that have been placed as congeners with it. I have transferred 182 species from *Stenoma* of Meyrick to other well established genera. Of these I have assigned 21 to *Anadasmus*, 103 to *Antaeotricha*, 1 to *Baeonoma*, 35 to *Cerconota*, 16 to *Gonioterma*, 1 to *Mothonica*, 1 to *Timocratica* and 4 to *Orphnolechia*. It will be noted that the species, with few exceptions, not only agree in type of genitalia but also in general habitus, as we should expect.

<sup>1</sup> *Exotic Microlepidoptera*, 1: 412, 1915.

I do not claim finality for all these new assignments but a casual glance will assure the observer that the associations are more natural than those previously made except in the residual "*Stenoma*". This great mass of species is still a heterogeny which will require close study, many new genera and much refinement, but it is not the purpose of this work to propose new generic names.

The genus *Dinotropa* is clearly Oecophorid on all characters and is accordingly transferred to the OECOPHORIDAE where it will be treated in its proper place.

When Meyrick described *Peleopoda semocrossa*<sup>1</sup> he placed it in the XYLORYCTIDAE. Later<sup>2</sup> he assigned the species to the OECOPHORIDAE but Busck<sup>3</sup> placed it in the STENOMIDAE because veins 6 and 7 of the hindwing are stalked. Certainly the stalking of veins 6 and 7 is rare in the OECOPHORIDAE but the genitalia unquestionably place the species there. I therefore transfer this species back to the OECOPHORIDAE.

Although Meyrick eventually recognised the family STENOMIDAE as distinct from the XYLORYCTIDAE he wrote as late as 1925<sup>4</sup> as follows: "(3) Your evidence as to *Setiostoma* being a Stenomid seems to me worthless; and I have no reason to suppose that your grounds for separating the XYLORYCTIDAE and STENOMIDAE would be any more convincing."

The family XYLORYCTIDAE was proposed by Meyrick in 1890<sup>5</sup> for a group of Australian genera and species characterised by a short cross-vein between the cell and vein 8 of the hindwing which the author, at that time, claimed to be ". . . invariably present." As time went on, Meyrick broadened his concept of the family and included in it genera and species from many tropical and temperate regions of the world and not only assigned many of his own genera to this family but included those of other authors. The thirty Meyrick genera treated in this work, assigned by him to the XYLORYCTIDAE, comprise a large assortment of types and representatives of several families. Of these genera only four, *Amorbaea*, *Epichostis*, *Linoclostis* and *Nephantis*, possess the cross-vein between the cell and vein 8 on which Meyrick laid so much stress. Two other genera, *Neospastis* and *Synchalara*, have vein 8 almost anastomosing with the cell, indicating a tendency to the formation of a cross-vein, and in the genus *Phthonerodes* vein 8 fuses along the cell for more than one-third its length.

*Amorbaea*, *Epichostis*, *Linoclostis* and *Nephantis* form a group of closely allied genera in which there is no blind-sac in the aedeagus and the abdomen is spined. *Epichostis stelota*, however, is misplaced and is hereby transferred to the OECOPHORIDAE. In the hindwing of *Nephantis* veins 6 and 7 are stalked but in the other three genera veins 6 and 7 are well separated and divergent. In *Phthonerodes* the blind-sac of the aedeagus is absent but it is present in *Synchalara* and *Neospastis*.

The following genera have veins 6 and 7 of the hindwing stalked and have no cross-vein between vein 8 and the cell: *Aeolanthes*, *Amphitriasis* (synonym of *Odites*), *Antithyra*, *Antolaea*, *Epimactis*, *Myriopleura* (synonym of *Odites*), *Procometis*, *Prothamnoides*, *Rhizosthenes*, *Thymiatriis*, *Trichernis* (synonym of *Odites*) and *Tryptherantis*.

Aside from the two features mentioned above, there is little to recommend the close association of these genera and much less to support their relationship to XYLORYCTIDAE (s. str.). In the genus *Antolaea* the gnathos is divided into two spined

<sup>1</sup> *Exotic Microlepidoptera*, 4: 13, 1930.

<sup>3</sup> *Lepidoptera Catalogus*, Part 67, p. 8, 1935.

<sup>4</sup> Meyrick to Busck: Thornhanger, Marlborough, 27.4.25.

<sup>5</sup> *Trans. R. Soc. S. Australia*, 13: 23, 1890.

<sup>2</sup> *Genera Insectorum*, fasc. 180: 188, 1925.

knobs and the aedeagus has a blind-sac. The character of the divided spined gnathos is shared by the Meyrick species placed in the genus *Acria* Stephens, by the two species *Durrantia montivola* and *D. flaccescens*, and *Odites navigatrix*, but none of them has the blind-sac of the aedeagus. The spined gnathos is a common character in the OECOPHORIDAE and these species appear to be a development of that family. We cannot place them in the OECOPHORIDAE at present because of the stalking of veins 6 and 7 of the hindwing, and because we have no supporting evidence from larvae for such an association.

The genus *Aeolanthes* presents a peculiar but highly characteristic type of male genitalia in which the aedeagus is disproportionately large and lacks the blind-sac, the harpes are variously shaped and ornamented and always reduced, and the uncus assumes various shapes, but it is always present. The females generally have double signa of dentate plates but at least one species (*sagulata*) possesses no signum at all.

The species referred to the genus *Odites* or its synonyms conform very much to type in form of genitalia: the transtilla usually exhibits strong development of the lateral lobes. The females are diverse and, at present, do not give much help in delimiting the genus. The true species of *Odites* possess a peculiar type of sharply beaked gnathos, which is directed anterad, and a long narrow tegumen. In this genus Meyrick has placed such atypical species as *brachyclista*, *concreta*, *continua*, *hermetica*, *mistharma*, *sphenodontis* and *spoliatrix* which must ultimately be transferred elsewhere. *Rhizosthenes* possesses the same type of gnathos as *Odites*.

The genus *Epimactis* is extremely close to *Odites*, and indeed may be a synonym but, as veins 3 and 4 of the hindwing are united, I am maintaining its identity for the time being.

*Thymiatris* and *Tryptherantis* are very closely related, having symmetrical male genitalia with a semi-tubular anellus, broadly attached harpe with clasper, aedeagus without blind-sac and gnathos and uncus present.

Another group of genera, *Deloryctis*, *Metathrinca* and *Ptochoryctis* lack the cross-vein between vein 8 and the cell in the hindwing, veins 6 and 7 are well separated and divergent and the abdomens are spined. These genera are probably nearer the OECOPHORIDAE than the XYLORYCTIDAE.

I am illustrating species assigned by Meyrick to *Agriophara*, *Gemorodes* and *Letogenes* but, since I have not examined the types of those genera, I cannot determine whether or not the species are correctly placed.

Several other genera and species have been associated with the XYLORYCTIDAE by Meyrick and require special consideration at this point. *Amniodes* (synonym of *Terthreutis*: new synonymy) is hereby transferred to the TORTRICIDAE. *Rhapsodica* is also referable to the TORTRICIDAE and is hereby transferred. *Thyrsomnestis* has already been transferred to the STENOMIDAE, where it probably belongs, though it is atypical of that family. *Plocamosaris* (synonym of *Noeza*: new synonymy) was described in the XYLORYCTIDAE and later transferred to the OECOPHORIDAE by Meyrick. The genus is referable to the GELECHIIDAE, as clearly indicated by the genitalia and its obvious close relationship to the types of both *Noeza* and *Neochrista*, and is hereby transferred to that family. *Leistogenes* also belongs in the GELECHIIDAE, as revealed by genitalic examination, and is hereby transferred to that family.

Meyrick<sup>1</sup> described *Asapharca nephelomicta* from New Mexico, but it does not seem

<sup>1</sup> *Exotic Microlepidoptera*, 3: 555, 1930.

likely that the American *nephelomicta* is truly congeneric with the African species of *Asapharca* and, in fact, the female genitalia exhibit Gelechioid features rather than Xyloryctoid characters. Since only the type female is known the species will be left in Meyrick's XYLORYCTIDAE, with reservations.

To this family we must add the genus *Lasiodictis* which was described in the GLYPHIPTERYGIDAE. I hereby transfer *Lasiodictis* to the XYLORYCTIDAE.

The family GELECHIIDAE, as at present constituted, is one of the largest families of Microlepidoptera and is world-wide in distribution. In this work I am considering only 226 genera, assigned by Meyrick to this family, although the family includes far more than that number. The proper restriction of the family will require many years of careful study.

One of the principal characters used to separate a Gelechiid from other species with similar venation is the absence of vein *rc* of the forewing. This character still holds in the vast preponderance of genera but *rc* is present in *Anastreblotis*, *Apethistis*, *Autosticha*, *Chlorolychnis*, *Hierangela*, *Homaloxestis*, *Steremniodes* and *Stochastica*. Some of these, however, are questionably Gelechiids and the presence of this vein may be abnormal in the other cases. All too frequently only a single specimen was available for examination so the extent to which the presence of this vein is exhibited in a given species could not be ascertained.

The above genera are included in two large, distinguishable groups of genera within the family. The separation of these two groups of genera is based on the presence or absence of a cross-vein between vein 8 and the cell of the hindwing. This cross-vein is present in *Acribologa*, *Agathactis*, *Ageliarchis*, *Agriastis*, *Alsodryas*, *Anastreblotis*, *Anathyrstis*, *Anomoxena*, *Anthistarcha*, *Arotromima*, *Atasthalistis*, *Axyrostola*, *Battaristis*, *Brochometis*, *Bucolarcha*, *Calamotypa*, *Calyptrotis*, *Carbatina*, *Catoptristis*, *Cerycangela*, *Chalcomima*, *Charistica*, *Chelophoba*, *Chthonogenes*, *Clepsimacha* (= *Cratinitis*), *Coconympha*, *Coleostoma*, *Compsolechia*, *Cotyloscia*, *Crasimorpha*, *Crossobela* (? too badly damaged), *Cymotricha*, *Deimnestra*, *Desmophylax*, *Dissoptila*, *Eripneura*, *Erythriastis* (? no hindwing), *Ethmiopsis*, *Ethrostoma*, *Eunebristis*, *Eupolis*, *Eustalodes*, *Glycerophthora*, *Hapalonoma*, *Haplochela*, *Holaxyra*, *Homalochelas*, *Hypelictis*, *Illingiotes*, *Leistogenes*, *Locharcha*, *Lophaeola*, *Metabolaea*, *Meteoristis*, *Molopostola*, *Musurga*, *Myrophila*, *Mythographa*, *Noeza* (= *Neochrista*, = *Plocamosaris*, new synonymy), *Orsodytis*, *Oxycryptis*, *Pachnistis*, *Pachygenia*, *Pachysaris*, *Paralectra*, *Pessograptis*, *Phrixocrita*, *Phylopatris*, *Pilocrates*, *Platyedra*, *Plexippica*, *Porpodryas*, *Promolopica*, *Prophoraula*, *Psamathoscopa*, *Rhynchotona*, *Schemataspis*, *Semiomeris*, *Semophylax*, *Sitotroga* (= *Nesolechia*, new synonymy, = *Syngenomictis*), *Sorotacta*, *Sterrhostoma*, *Stiphrostola*, *Symphanactis*, *Syncratomorpha*, *Taphrosaris*, *Telephila*, *Teuchophanes*, *Thyrsostoma*, *Tornodoxa*, *Trachyedra*, *Trichembola*, *Xenorrhyma*, *Zalithia* and *Zomeutis*.

In the following group of genera the cross-vein between vein 8 and the cell is absent: *Anthinora*, *Apethistis*, *Aphanostola*, *Apocritica*, *Asarista*, *Asmenistis*, *Aulidiotes*, *Autosticha* (= *Epicoenia*), *Beltheca* (= *Anterethista*), *Calliprora*, *Chlorolychnis*, *Cnaphostola*, *Colonanthes*, *Commatica*, *Compsosaris*, *Crambodoxa*, *Deroxena*, *Elasiprora*, *Empedaula*, *Encolapta*, *Encolpotis*, *Ephysteris*, *Eristhenodes*, *Euzonomacha*, *Evippe* (= *Tholerostola*, new synonymy), *Hapalosaris*, *Harpagandra*, *Heliangara*, *Hierangela*, *Homaloxestis*, *Inotica*, *Ischnodoris*, *Isembola*, *Isophrictis*, *Istrianis*, *Latrologa*, *Meridorma*,

*Mnesistega*, *Nartheoceros*, *Oxylechia*, *Palintropha*, *Paradoris*, *Parallactis*, *Pavolechia* (= *Desmaucha*), *Pelocnistis*, *Pharangitis*, *Phatnotis*, *Pitycona*, *Proselotis*, *Protolychnis*, *Semnostoma*, *Stagmaturgis*, *Steremniodes*, *Stochastica*, *Synactias*, *Syncathedra*, *Thiotricha*, *Thripsigenes* (= *Lioclepta*, new synonymy), *Toxotacma* and *Tryptherogenes*.

There appears to be a distinct correlation between the absence of 1c of the forewing and the presence of a cross-vein between vein 8 and the cell of the hindwing although *Anastreblotis* has 1c present in the forewing and a cross-vein between vein 8 and the cell of the hindwing. The type species of this genus, *A. calycopa* Meyrick, a female, has the pattern and facies of a Blastobasid and may well belong in that family. It will be noted also that the venation of the forewing is that of the BLASTOBASIDAE.

In the second group, those without the cross-vein between vein 8 and the cell of the hindwing, vein 1c is absent in the great majority of genera but it is present in *Apethistis*, *Autosticha*, *Chlorolychnis*, *Hierangela*, *Homaloxestis*, *Steremniodes* and *Stochastica*. *Autosticha* is doubtfully Gelechiid, not only on venational characters but also because of its atypical genitalia and the refuse-feeding habit of its larva.

The GELECHIIDAE characteristically have smooth abdomens but the abdomens of at least two genera, undoubtedly referable to this family, are clothed with spines. These are *Mnesistega* and *Pavolechia* Busck (= *Desmaucha*).

The condition of veins 6 and 7 of the hindwing, i.e. stalked, approximate, etc., has been used frequently to determine the family position in GELECHIIDAE but there is no relation between the condition of these two veins and the assignment of any given genus to this family; nor is there any relation between the condition of these two veins and the assignment of genera to either of the two groups I have discussed above. Veins 6 and 7 may be united as in *Agathactis*, *Calyptrotis*, *Pachygenia*, *Elasiprora*, *Hapalosaris*, and *Pitycona*; stalked as in *Anastreblotis*, *Homalochelas*, *Metabolaeta*, *Pachmistis*, *Pessograptis*, *Aphanostola*, *Phatnotis* and many others; approximate at base as in *Acribolga*, *Eupolis*, *Phrixocrita*, *Sorotacta*, *Trachyedra* and others; connate as in *Arotromima*, *Cotyloscia*, *Symphanactis* and *Calliprora*, or widely separate as in *Atasthalistis*, *Glycerophthora*, *Trichembola*, *Crambodoxa*, *Empedaula*, *Pelocnistis* and some other genera. In addition there are varying degrees of proximity or divergence of these two veins.

Occasionally anomalous conditions appeared which may or may not be normal for the genera but, because of the paucity of material available for study, it was impossible to determine whether or not the specimens examined were freaks. In the hindwing of *Symphanactis* there is a very distinct, well developed "vein 9" from the base of the wing to costa. Vein 7 and vein 8 of the hindwing of *Isembola* are both stalked, thus producing ten veins. These conditions may not be significant but may well indicate hereditary traits peculiar to the species.

The following genera possess characters which preclude their retention in the GELECHIIDAE. They are: *Alciphanes*, *Anaxyrina*, *Athymoris*, *Aulidiotis*, *Brachyerga*, *Carodista*, *Cophomantis*, *Crocogma*, *Cynicocrates*, *Cynicostola*, *Deltoplastis*, *Demiophila*, *Dinochares*, *Dolichotorna*, *Doxogenes*, *Encrasima*, *Enthetica*, *Epharmonia*, *Eridachtha*, *Gasmara* Walker (= *Antiochtha*), *Habrogenes*, *Heteralcis*, *Heterodeltis*, *Heteroderces*, *Hygroplasta*, *Hyperochtha*, *Hypochasmia*, *Hyptiastis*, *Irenidora*, *Lecithocera*, *Lysipatha*, *Macrernis*, *Merocrates*, *Mnesteria*, *Monerista*, *Neocorodes*, *Nosphistica*, *Olbothrepta*, *Oxygnostis*, *Parelliptis*, *Periphorectis*, *Phanoschista*, *Philarachnis*, *Philoptila*, *Placanthos*,

*Protobathra*, *Psammoris*, *Pseudocrates*, *Sarisophora* (?), *Scaeostrepta*, *Semnochoa*, *Sphaerolbia*, *Sphagiocrates*, *Stelechoris*, *Stryphnocolpa*, *Technographa*, *Teucrodoxa*, *Thymbristis*, *Torodora* and *Trichoboscis*.

For these genera I propose the new family TIMYRIDAE based on *Timyra* Walker, *List of the specimens of Lepidopterous insects in the collections of the British Museum*, vol. 29, p. 782, 1864. (*Typus generis*.—*Timyra phycisella* Walker, l.c. p. 783 [by monotypy].)

In addition to the genera listed above the following are also hereby transferred from the GELECHIIDAE to the TIMYRIDAE: *Crocantes* Meyrick (1886), *Frisilia* Walker (1864), *Thubana* Walker (1864) and *Tisis* Walker (1864). No doubt others that I have been unable to study are referable here also.

This family is peculiar in that the venation of the genera varies widely, from complete, as in *Brachyerga* and *Carodista*, to that in which there is a great reduction as in *Oxygnostis* and *Phanoschista*. In genera in which the venation is greatly reduced the cell is open and the upper surface of the hindwing is often modified by sex-scaling or hair-pencils in the male. The family is characterised also by considerable modification of the labial palpus of the male. The male genitalia are symmetrical, harpe broadly attached at base, and are characterised by a beak-like gnathos turned anterad. The aedeagus is stout and the vesica is armed with strong cornuti. The vesica enters the aedeagus ventrally or through the proximal end. The female genitalia are various but if the signum is present it is generally a dentate plate.

The affinities of this family appear to be with *Odites*, and related genera of the XYLORYCTIDAE, by reason of the similar gnathos. The signum of the female suggests derivation from the OECOPHORIDAE.

The following genera: *Colpomorpha*, *Cyrictodes* and *Pedioxestis*, are hereby transferred from the GELECHIIDAE to the OECOPHORIDAE. The genus *Harpograptis* is hereby transferred from the GELECHIIDAE to the COSMOPTERYGIDAE and the Chinese genus *Irenidora*, a borderline genus, is assigned to the BLASTOBASIDAE with its near relative, the North American *Gerdana* Busck.

*Orygocera amphichelota* is hereby transferred from the OECOPHORIDAE to the GELECHIIDAE and *Athrinacia cosmophragma* is removed from the GELECHIIDAE and assigned to the OECOPHORIDAE. In the foregoing pages I have already disposed of *Leistogenes* and *Plocamosaris*, assigned to the XYLORYCTIDAE and OECOPHORIDAE respectively by Meyrick, and I hereby transfer *Ischenophenax* from the OECOPHORIDAE and *Plexippica* from the HYPONOMEUTIDAE to the GELECHIIDAE.

The structure of the genitalia of the male of *Strepsimanus scieropis* Meyrick supports Meyrick's contention that the family STREPSIMANIDAE is a derivative of the XYLORYCTIDAE.

The family PHYLOPTILIDAE appears to be very near the GELECHIIDAE, which view is supported by genitalic structures.

In 1932<sup>1</sup> Meyrick proposed the family name SCAEOSOPHIDAE for a group of genera, *Scaeosopha*, *Allotalanta*, *Cyphothyris*, etc., which he had formerly placed in the family OECOPHORIDAE. This family cannot be maintained because the genera and species must be assigned to other well established and recognised families. *Allotalanta*, *Bathraula*, *Cyphothyris*, *Helicacma*, *Protogrypa*, *Scaeosopha* and *Scalideutis* are hereby

<sup>1</sup> *Exotic Microlepidoptera*, 4: 332.

transferred to the COSMOPTERYGIDAE on the basis of the genitalic structures which are characteristically those of that family. *Allotalanta xanthacma* is clearly Oecophorid and is hereby transferred back to the family OECOPHORIDAE.

Meyrick's OECOPHORIDAE was a very broad concept, and I have shown in the preceding pages that it is necessary to remove certain genera from the family and add certain others which obviously belong here. It is likewise necessary to transfer a large number of species to genera in other families and reallocate others in this family.

The OECOPHORIDAE constitute a homogenous family usually consistent in venational characters, and in type of genitalia the exceptions are few. Vein 1c of the forewing is usually preserved at the margin of the wing and this is correlated with separate and slightly divergent veins 6 and 7 of the hindwing. The family may be divided into two more or less natural groups based on the gnathos. The gnathos of one group is spined and usually terminates in a round or oval knob, but sometimes is divided into two similar elements; the gnathos of the other group is slender or stout but generally smooth and never terminates in a spined knob. The female genitalia vary but the signum, if present, is usually in the form of a sclerotised, dentate plate. The abdomen may be spined or smooth.

Meyrick recognised the following genera in the OECOPHORIDAE (he recognised others not covered in the scope of this work): *Aeolarcha*, *Aeolernis*, *Agriotorna*, *Alomenarcha*, *Anacathartis*, *Anacoemastis*, *Anchonoma*, *Anorcota*, *Archisopha*, *Arctoscelis*, *Astiarcha*, *Atelosticha*, *Atopophrictis*, *Auxotricha*, *Calliphractis*, *Chariphylla*, *Chrysonoma*, *Comotechna*, *Critoxena*, *Delosaphes*, *Dolitechna*, *Elaeonoma*, *Elaphrerga*, *Eomichla*, *Eonympha*, *Epimecyntis*, *Epimoryctis*, *Epiphractis*, *Erithyma*, *Erotis*, *Eupselia*, *Exosphrantis*, *Halimarmara*, *Haploscopa*, *Heterodmeta*, *Heterozyga*, *Himotica*, *Homosaces*, *Horomeristis*, *Ischnophenax*, *Idiocrates*, *Lactistica*, *Langastis*, *Lasiochira*, *Lepidechidna*, *Lysigrapha*, *Macarocosma*, *Macrococma*, *Macrosaces*, *Meleonoma*, *Melochrysis*, *Mesothyrsa*, *Mylothra*, *Octasphales*, *Orsimacha*, *Orsotricha*, *Oxycharis*, *Pelochares*, *Pelomimas*, *Periacma*, *Perilachna*, *Petalostoma*, *Phalarotarsa*, *Phanerodoxa*, *Philarga*, *Philomusaea*, *Phyltronoma*, *Picrotechna*, *Porthmologa*, *Promalactis*, *Protonostoma*, *Psaltica*, *Pseudocentris*, *Psittacastis*, *Scoliographa*, *Siderograptis*, *Sphaerelictis*, *Stereodytis*, *Struthoscelis*, *Scyllochitis*, *Syntomaula*, *Tachystola*, *Terthrotica*, *Trachypepla*, *Triptologa*, *Tyrolimnas*, *Xenomicta*, *Xystoceros*, *Zatrichodes*, *Zemiocrita* and *Zygolepha*.

Of the above genera *Anorcota* and *Syntomaula* are immediately referable to the COSMOPTERYGIDAE and are hereby transferred to that family. Meyrick never recognised the assignment of *Triclonella* Busck<sup>1</sup> to the COSMOPTERYGIDAE and all but one of his species described in *Triclonella* must, therefore, be transferred to the COSMOPTERYGIDAE. These are: *Triclonella calyptroides*, *T. elliptica*, *T. etearcha*, *T. iphicleia*, *T. philantha*, *T. pictoria*, *T. trachyxyla*, *T. triargyra* and *T. turbinalis*. One species, *T. anachasta*, must be removed from the genus *Triclonella* and assigned to the BLASTOBASIDAE. The genera *Critoxena* and *Syndroma* are also hereby transferred to the BLASTOBASIDAE.

Meyrick's genus *Borkhausenia* is also composite. Although most of the species are properly referred to the OECOPHORIDAE a few belong elsewhere. *B. longa* and *B. leucoritis* have been removed previously<sup>2</sup> and transferred to the COSMOPTERYGIDAE. *B. exstimulata* is likewise referable to the COSMOPTERYGIDAE and is hereby transferred to that family.

<sup>1</sup> Busck, A., *Proc. Ent. Soc. Washington*, 34: 17, 1932.

<sup>2</sup> Clarke, J. F. Gates, *Can. Ent.*, 74: 17, 1942.

The genitalia of the species transferred to the COSMOPTERYGIDAE are so characteristic there can be no doubt about their position.

Other species referable and hereby transferred to the COSMOPTERYGIDAE are: *Promalactis synclina*, *Cryptolechia chordostoma*, *C. synclera*, *Meleonoma implexa*, *Alloclita delozona*, *A. reflua*, *Pseudodoxia crocomitra* and *Mompha pentapyrga*.

The genus *Promalactis* is composite but *P. isothea* and its type species, *P. holozona*, present a unique case. In the males of both of these species the harpe is equipped with a movable, articulated appendage, a structure which, to my knowledge, is not found elsewhere in the Lepidoptera. This genus (s. str.) will probably require a new family. Certain other species, at present known only from females, will undoubtedly have to be associated with these two species, but further study will be required to establish the limits of this unique and interesting group.

The following African and Indian species, all very closely related, cannot be retained in the OECOPHORIDAE and are hereby transferred to the GELECHIIDAE: *Cryptolechia arvalis*, *C. nyctiphronas*, *Orygocera amphichelota*, *O. liliacea*, *O. propycnota* and *O. sphacterias*. The genus *Ischnophenax* is also referable to the GELECHIIDAE and is hereby transferred.

The genera *Auxotricha*, *Comotechna*, *Halimarmara* and *Picrotechna* have vein 5 of the hindwing nearer to 6 than to 4, usually a positive Ethmiid character, but the genitalia, with the possible exception of *Comotechna*, favour retention of these genera in the OECOPHORIDAE.

*Aeolernis*, *Alomenarcha*, *Archisopha*, *Himotica*, *Meleonoma*, *Mesothyrsa*, *Orsotricha*, *Oxycharis*, *Periacma*, *Petalostoma*, *Philarga*, *Psaltica*, *Struthoscelis*, *Triptologa* and *Zygotlopha*, have vein 1c absent in the forewing though otherwise exhibiting chiefly Oecophorid characters. Of these genera *Orsotricha* and *Petalostoma* are hereby transferred to the GELECHIIDAE and the others are retained, with reservations, in the OECOPHORIDAE.

*Epiphraetis* and *Struthoscelis* exhibit venational characters which are unique while retaining other features which are clearly Oecophorid. The former possesses a cross-vein between 7 and 8 of the hindwing *beyond the cell*, and both have an accessory cell in the forewing. The accessory cell of *Epiphraetis* is less well defined than that of *Struthoscelis* and the discal cell of the latter is greatly shortened.

Three genera, *Mylothra*, *Xystoceros* and *Zemiocrita* have veins 6 and 7 of the hindwing stalked. This is not an Oecophorid character, but in spite of it *Zemiocrita* is retained in the OECOPHORIDAE since it exhibits other Oecophorid features. The Indian *Mylothra* and *Xystoceros* are borderline cases and both are nearly related to the North American *Gerdana* Busck. These two genera I now assign to the BLASTOBASIDAE since they are better accommodated there than elsewhere.

The species assigned by Meyrick to the COSMOPTERYGIDAE and BLASTOBASIDAE appear, with a few possible exceptions, to have been properly placed and require no special comment. As Meyrick did not distinguish between the COSMOPTERYGIDAE and MOMPHEIDAE, and since the treatment of these families in this work is largely incidental, no further comment will be made.

The small family METACHANDIDAE, confined to the African and Oriental Regions, is characterised by the loss of one or more veins from at least one wing but usually one from each. Although two types of genitalia are found in the family as it now exists,

one type, in which the cucullus is divided and the signum is three-pointed, predominates. This type suggests a close affinity to the Gelechiid-Oecophorid complex; the second type suggests a closer relationship to the Blastobasids.

Meyrick always considered the ETHMIIDAE and HYPONOMEUTIDAE synonymous, despite the fact that the former are Gelechioids, and maintained a distinction between the HYPONOMEUTIDAE and PLUTELLIDAE. These last two families are inseparable, as indicated by structures of both immature and adult stages.

The family ETHMIIDAE is already well established and all the species described in the genus *Ethmia* by Meyrick are referable to this family. The genera *Agrioceros* and *Probolacma* are also hereby transferred to the ETHMIIDAE. *Idioptila*, described as a Gelechiid, has previously<sup>1</sup> been referred to this family as a synonym of *Pyramidobela* Braun. One of the strongest characters of this family is the segmented harpe of the male.

The genera of the HYPONOMEUTIDAE fall into two large groups on the basis of the male genitalia. The first group consists of genera in which the harpe is ample, the aedeagus is slender and the uncus is divided into two elements. Unfortunately the males of several genera are not known to me and I am unable to place them, but the following fall in the first group with *Hyponomeuta*: *Amiantastis*, *Calliathla*, *Chalconympha*, *Diaphragmistis*, *Epichthonodes* (?), *Litaneutis*, *Lycophantis*, *Metanomeuta*, *Orthosaris*, *Perisceptis*, *Philaustera* and *Tarphyscelis*.

In the second group the uncus is a single element and this and the harpe suggest a relationship with the XYLORYCTIDAE rather than with the other HYPONOMEUTIDAE. Genera in this group are: *Anticrates* (= *Pyrozela*), *Comocritis*, *Eriopyrrha*, *Lactura* Walker, *Spilogenes*, *Trichocirca* (= *Telosphrantis*) and *Thalassonympha*.

Certain of the genera retained in the HYPONOMEUTIDAE require further comment. The monobasic genus *Pronomeuta* exhibits extraordinary features in both wing venation and genitalic type. In the forewing of the type species, *sarcopis*, the medial vein is strongly developed thus dividing the discal cell into two almost equal parts, and there is a well developed accessory cell lying between veins 6 and 10. The genitalia strongly suggest a Tineid affinity by the form of the harpes and the unusually great development of the vinculum.

The genus *Lamyristis* is noteworthy because of the presence of seven bristles in the frenulum of the female, the degeneration of the radial vein of the forewing and the tendency to form accessory cells.

Several genera, now placed in the HYPONOMEUTIDAE, require reallocation and I hereby transfer *Loxozya* to the OECOPHORIDAE, *Orinympha* to the SCYTHRIDIDAE and *Platybathra* to the COSMOPTERYGIDAE. The last genus is very closely related to *Syntetrernis*, already placed in the COSMOPTERYGIDAE by Meyrick, and possesses the same type of genitalia.

*Metharmostis* will probably have to be assigned to the COSMOPTERYGIDAE on the basis of the female genitalia of *M. asaphaula* which show a striking similarity to those of *Stilbosis devoluta*, already placed in that family.

*Stichotactis* is very closely related to, if not congeneric with, *Homadaula*, and is hereby transferred to the GLYPHIPTERYGIDAE.

*Nosymna ochrochorda* appears to be incorrectly placed in the HYPONOMEUTIDAE

<sup>1</sup> Meyrick, *Exotic Microlepidoptera*, 3: 414, 1928.

but, not having seen Walker's type of the genus, I cannot state whether or not *ochrochorda* is properly assigned generically.

The GLYPHIPTERYGIDAE present no great problems except in the genus *Imma* in which appear many different forms of palpi, pattern and coloration, and in which we find species that seem to be transitional between the Microlepidoptera and the Macrolepidoptera. Indeed, it is here that we may look for the origin of the PHALAEINIDAE. Required study of the genus *Imma* is far beyond the scope of this work and can only be alluded to here.

The following families: TORTRICIDAE, OLETHREUTIDAE (=EUCOSMIDAE, *Auct.*), PHALONIIDAE, CARPOSINIDAE and CHLIDANOTIDAE, comprise a natural world-wide group which, though composed of closely related families, form definable entities, each component being rather easily separable from any other. There are a few cases, however, which present difficulties but this may be due more to our lack of understanding than to any particular peculiarity of the insects themselves.

In the family TORTRICIDAE only fifty Meyrick genera are being considered and, since nearly all of these are already properly placed and require no special comment, I shall discuss only those which require attention at this point.

First it should be pointed out that the family TORTRICIDAE characteristically possesses vein 1c of the forewing, no cubital pecten on the hindwing, symmetrical male genitalia with broadly attached harpe and moderate to slender aedeagus and a subtriangular, somewhat folded, anellus. The signum, when present, consists of a single stellate plate, a sclerotised band or a single thorn with a large bulbous base. The above, of course, are not all the characters involved in the definition of the family, but will be adequate here.

Of the fifty genera considered in this work *Acroplectis*, *Deltobathra*, *Diactenis*, *Mnesipyrga*, *Peteliacma* and *Proselena* lack vein 1c of the forewing. *Mnesipyrga* is referable to the PHALAEINIDAE and is hereby transferred to that family. It belongs in the *Acidaliodes* complex, having the characteristic spiculate bursa copulatrix of that group, a simple 1b of forewing and no vein 5 of hindwing. The other genera, except *Diactenis* which has aberrant venation, have little to recommend their assignment to other families.

Except for synonymy, which will be treated in Volume III, there are no other changes of genera required at this point.

Meyrick's concept of *Eulia* was broad and loose and he has placed a great assortment of unrelated species in it. Many of the species he included in *Eulia* will be re-assigned, elsewhere in this work, and still others will require the erection of new genera to contain them and provide a proper classification. What is true of *Eulia* is, to a lesser extent, true of other genera and a reshuffling of many species will be unavoidable.

A unique group in the TORTRICIDAE, consisting of the four closely related genera *Ardeutica*, *Atteria*, *Polyortha* and *Pseudatteria* is peculiar in that the harpe of the male is split longitudinally along the ventral edge, forming a longitudinal pocket for the reception of an abdominal hair-pencil. The four genera are South American.

*Tortrix noctivola* is referable to the OLETHREUTIDAE and is hereby transferred to that family. *Arotrophora balsamodes* is hereby transferred to the PHALONIIDAE.

*Tortrix crocomis* lacks vein 1c of forewing but is retained in the family TORTRICIDAE with doubt because the abdomen of the unique type is missing.

Among the five Tortricoid families the OLETHREUTIDAE are the most closely related to the TORTRICIDAE. The genitalia of this family, however, serve to distinguish any member from any species of Tortricid. In fact, there are no genitalia in the Lepidoptera that can be easily confused with those of the OLETHREUTIDAE. The peculiar anellus with the aedeagus strongly fused to it is unique and is diagnostic of the family. The female of any Olethreutid may be distinguished from any Tortricid, or from species of other families of this complex, by the signum, which consists of a single or double thorn *without* large bulbous base, or a pair of small dentate cones. Exceptions to this are *Polychrosis inflicta*, *Proschistis lucifera*, *Argyroploce mniopyrrha*, *A. petrumacha*, *A. sideroxyla*, *A. streblopa* and *A. torquata*, but other characters leave no doubt as to their family position.

In this family most species are assigned to other than Meyrick genera and particularly to *Argyroploce* without regard to subfamily distinctions. Meyrick's *Argyroploce* is a synonym of *Olethreutes* Hübner and all species placed under that name by him will be transferred to the genus *Olethreutes*. In this work, because of its arrangement and method of presentation in subsequent volumes, subfamily position will be ignored but the fact remains that in a correct systematic arrangement the subfamilies must be recognised. The genera, as conceived by Meyrick, like *Eulia* and *Stenoma* contain large assemblages of unrelated forms.

It is interesting to note, however, that in the assignment of hundreds of species to the OLETHREUTIDAE Meyrick referred only two Tortricids to this family. A splendid record! These two species are *Argyroploce ornithotypa* and *Eucosma torrens* which I hereby transfer to the TORTRICIDAE.

The Tortricoid family PHALONIIDAE provides a multitude of genitalic types but a great constancy in structure and facies and, as far as known, vein 1c of the forewing is *never* present in the PHALONIIDAE. I do not know of a single exception. The absence of 1c immediately excludes TORTRICIDAE (except five genera) and all OLETHREUTIDAE.

The great bulk of PHALONIIDAE have been placed in the genus *Phalonia*, but this genus, as it now stands, is another "wastebasket" containing several distinct genera. Reallocations in this family will necessarily be many. *Hysterosia zophocosma* and *Phitheochroa psychrodora* are both referable to the OLETHREUTIDAE and are hereby transferred to that family.

The fourth family of this complex, the CHLIDANOTIDAE, is confined to the Indian Region, Borneo and Fiji. In this family Meyrick placed *Archimaga*, *Branchophantis*, *Chlidanota*, *Electracma*, *Metreranis* and *Trymalitis*. The CHLIDANOTIDAE are characterised by the absence of 1c *and* one other vein (7 or 9) in the forewing plus the absence of cubital pecten from the hindwing. The male genitalia are simple, Xyloryctoid in character with ample, simple harpe, simple uncus, broadly triangular anellus and moderate aedeagus. The ovipositor lobes are distinctly Tortricoid but the signum consists of a central plate with a heavy pecten of long sclerotised spines.

Although *Electracma* undoubtedly belongs here the forewing shows twelve veins by the freakish terminal forking of vein 7. It might be argued that 7 and 8 are long-stalked and that vein 9 is present but I think Meyrick's interpretation of the veins is correct and that vein 9 is absent. It appears that the apical section in the type specimen of *hemichroa* is deformed, as is clearly the case in the type of *Metreranis (ochrolina)*, in which degeneration of the apical veins has taken place. It may be inferred from these

two examples that malformation of this sort is not unusual. This family appears to be intermediate between the PHALONIIDAE and the OLETHREUTIDAE. In my initial statement concerning this family, I limited its distribution to a small area of the Old World Tropics but it seems very likely that certain tropical American species will be referable to the CHLIDANOTIDAE.

In the last of the Tortricoid families dealt with in this work, the CARPOSINIDAE, we encounter a group which cannot be easily confused with the other four. In this family wing characters alone will serve for distinction. The forewing is tufted and the hindwing lacks veins 4 and 6, the latter often represented by a fold from about the middle of the discocellulars. The cell of both wings is usually closed but in *Picrorrhyncha* both are open. The female genitalia of this genus are also aberrant for the family and the genus may be misplaced here.

In the genitalia we find characters which generally establish the family position although a few species, apparently correctly placed here, deviate from the general pattern. Characteristically the aedeagus is very slender proximally but is greatly enlarged and heavily armed distally. In the female the signum usually consists of two forked elements but in a few species, *Commataarcha palaeosema*, *Meridarchis eremitis*, *M. heptaspila*, *Paramorpha aulata*, *P. laxenta* and one or two others, this condition does not exist.

Meyrick did not distinguish between the TINEIDAE and ACROLOPHIDAE and is supported in this view by some contemporary workers. The larvae and adult characters, in my opinion, justify such a separation and, in this work, I regard them as distinct families. The scope of this work is limited to a consideration of the American fauna in these two families. In the TINEIDAE vein 7 runs to apex or costa, generally the latter, and in the ACROLOPHIDAE it runs to termen. The basal whorl of scales on each segment of the antenna is reduced to a whorl of bristles in the TINEIDAE, but in the ACROLOPHIDAE the two whorls are equally developed.

Since Meyrick made no distinction between these two families no criticism of his assignment of genera is warranted. *Brachysymbola* appears to be nearly related to *Acrolophus* and is hereby transferred to the ACROLOPHIDAE. Meyrick's genus *Acrolophus* contains several species of several genera and these will be properly placed in a subsequent volume.

# ACKNOWLEDGMENTS

SINCE the inception of this task I have become indebted to a large number of individuals to whom I wish to express my sincere appreciation for the help received.

To Mr. N. D. Riley, Keeper of Entomology, who suggested the project, and the Trustees of the British Museum (Natural History) who placed every facility at my disposal and without whose support the plan could not have been carried to conclusion, and to Mr. W. H. T. Tams, in charge of Lepidoptera, a constant source of inspiration and encouragement, an especial debt is due.

My sincere thanks are due my own superiors, Mr. C. F. W. Muesebeck, Leader, Division of Insect Identification and the late Dr. P. N. Annand, Chief, Bureau of Entomology and Plant Quarantine for their enthusiastic support of this undertaking and for the release from other duties which enabled me to carry out my investigations abroad. To Dr. Alexander Wetmore, Secretary, Smithsonian Institution, I owe my thanks for necessary expenses and for providing complete photographic equipment. I wish to express my appreciation also to Mr. Paul O. Nyhus, Agricultural Attaché, United States Embassy, London, and to his staff who aided me on many occasions and who supplied much needed items such as typing paper and index cards, unobtainable in London at that time, and helped me in many other respects.

To the following individuals I am much indebted for information concerning the many scattered types in institutions and private collections: To Dr. A. J. T. Janse, Transvaal Museum, Pretoria, South Africa; to Dr. A. J. Hesse, South African Museum, Cape Town, South Africa; to M. J. Bourgogne and M. P. Viette, Muséum National d'Histoire Naturelle, Paris, France; to Professor Bruno Pittioni, The Naturhistorisches Museum, Vienna, Austria; to Dr. Ramon Agenjo, Instituto Español de Entomología, Madrid, Spain; to Mr. Elwood C. Zimmerman, The Bernice P. Bishop Museum, Honolulu, Hawaii for information concerning the types in that institution and in the collection of the Hawaiian Sugar Planters' Experiment Station, Honolulu, Hawaii; to Dr. H. Schouteden, Musée du Congo Belge, Tervueren, Belgium; to Dr. W. T. M. Forbes, Department of Entomology, Cornell University, Ithaca, New York; to Dr. M. L. Roonwal, Zoological Survey of India, Kaiser Castle, Banaras Cantt.; to Professor Dr. Ferdinand Pax, Museum für Natur- Völker- und Handelskunde, Bremen, Germany; to Professor Dr. Hans Sachtleben, Deutsches Entomologisches Institut, Berlin, Germany; to the late Professor G. D. Hale Carpenter, Hope Department, Oxford University Museum, Oxford, England; to Dr. R. T. M. Pescott, National Museum of Victoria, Melbourne, Australia; to Dr. A. Diakonoff, late of the Zoölogisch Museum en Laboratorim, Bogor, Java, and Dr. C. O. van Regteren-Altena for information on the types in the Rijks Museum van Natuurlijke Historie, Leiden, Holland; to Dr. A. B. Walkom and Mr. Anthony Musgrave, The Australian Museum, Sydney, Australia; to M. Le Marchand, Paris; to Victoria H. Raica, Muzeul de Istorie Naturală and Prince Aristide Caradja, Bucharest, Rumania; to Professor Dr. B. Klatt, Hamburgisches Zoologisches Museum und Institut, Hamburg, Germany; to Dr. J. N. Mukherjee, Indian Agricultural Research Institute, New Delhi, India; to Mr. E. A. Ellis, The

Castle Museum, Norwich, Norfolk, England; to Dr. W. R. B. Oliver, Canterbury Museum, Christchurch, C.I., New Zealand; to Tom Harrison, Curator, Sarawak Museum, Kuching, Sarawak; to Dr. H. Höne, Museum Alexander Koenig, Bonn, Germany; to Dr. H. G. Amsel, Buchenburg bei Peterzell, Baden, Germany; and to Mr. E. P. Wiltshire, British Consulate, Shiraz, Persia.

The following enthusiasts, who worked under my direction, are due special thanks for their interest in the project and their tireless efforts to bring it to a successful conclusion: Mr. John D. Bradley, Microlepidopterist, British Museum (Natural History), my fulltime assistant, who worked with me throughout the course of my stay and relieved me of many time-consuming tasks; Mr. Harold Malies, microscopist, of Southport, Lancs., England, Fellow of the Royal Microscopical Society, who made practically all the photomicrographs; Mr. Charles Owen Harman, medical student, from Brighton, England, who photographed very many of the wings and heads of the moths; the late Miss Hazel Rough, sculpturing student from Wellington, New Zealand, who made so carefully the more than 600 drawings of the venation of the types of the genera and by her ability, enthusiasm and charm won the admiration of her many friends in the Museum; Miss Margaret Chaborel of London and Mrs. Jacqueline Beatty of Paris who aided so extensively in bringing together the catalogue of species and handled the considerable correspondence with the many individuals who supplied information.

There are others who have helped in smaller, but nonetheless important ways, and to them I give my sincere thanks also.

## ILLUSTRATIONS

THE illustrations for volume I were made by Mr. M. G. Sawyers, staff photographer of the British Museum (Natural History) who made some of the "exploratory" photomicrographs in volume II also.

The remaining photomicrographs were made by Harold Malies on a Watson "Holophot". This apparatus, however, had to be adapted, by various devices, to photograph successfully all of the various types and sizes of genitalia. It is recognised that photomicrographs of genitalia are not always entirely satisfactory as a means of illustration but the immensity of the task made the use of this method mandatory. In some cases it has been necessary to use composite photomicrographs, exposures at different levels and part of one superimposed over the other, in order to bring out diagnostic details. In some cases I have added, also, sketches in lateral aspect to show essential details.

Most of the photographs of the wings and heads have been taken by Mr. Harman with a Leica camera equipped with a Leitz Elmar  $f=5$  cm., 1:3.5 lens. Extension tubes were used where necessary to enlarge the image on the film and all the prints were brought up to 3 by 4 inches. In a few instances the left wings were not in condition to be photographed and in such cases the right wings were photographed and the image reversed on the plate.

# CATALOGUE OF SPECIES

IN the pages immediately following is a catalogue of the species of Microlepidoptera described or named by Meyrick.

The purpose of this catalogue is not only to list the names and give references to the original descriptions, but also to indicate the disposition of the type when known. When a species was described a proposed repository for the type was sometimes given, but the type is not always to be found in the place indicated. Usually, however, no indication of the disposition of the type was given and it is assumed that these types were retained by Meyrick. Some have been lost and some have been destroyed and others are to be found in places other than indicated. As previously pointed out, when Meyrick synonymised one of his species with another, the two series were merged without reference to the type specimens. As a result of this practice at least one type [*Stenoma niphacma* labelled *S. chalastis* by Meyrick] was sent to August Busck of the U.S. National Museum, as an example of the valid species, yet this specimen should have been found in the Meyrick Collection.

In order to ascertain the locations of types I have written to many institutions and individuals and have been accorded a most hearty and helpful response. As a result of this generous co-operation it has been possible to acquire authentic information regarding the actual locations of several thousands of types in addition to those which I have seen, examined and authenticated myself. There are many more types in the British Museum that have not yet been studied or authenticated.

Following each reference is a symbol which represents the institution or collection in which the type will be found *providing the type has been verified*. If the location of the type is unknown no symbol will be found. If the type is lost or destroyed the words "Lost" or "Destroyed" are inserted. Meyrick proposed many substitute names for those which he found to be preoccupied. These have been marked "Sub".

The types of genera have been marked "\*" following the generic name of which the species is the type.

Below is a list of institutions and collections, with their appropriate symbols, in which the types will be found:

The British Museum (Natural History), London	(BM)
The United States National Museum, Washington, D.C.	(US)
The Transvaal Museum, Pretoria	(T)
The South African Museum, Cape Town	(SA)
The Muséum National d'Histoire Naturelle, Paris	(P)
The Naturhistorisches Museum, Vienna	(V)
The Instituto Español de Entomología, Madrid	(M)
The Bernice P. Bishop Museum, Honolulu	(BB)
The Hawaiian Sugar Planters' Experiment Station, Honolulu	(SP)

The Musée du Congo Belge, Tervueren, Belgium	(C)
The Department of Entomology, Cornell University, Ithaca, N.Y.	(CU)
The Zoological Survey of India, Kaiser Castle, Banaras Cantt.	(K)
The Museum für Natur- Völker- und Handelskunde, Bremen	(H)
The National Museum of Victoria, Melbourne	(MA)
The Deutsches Entomologisches Institut, Berlin	(D)
The Hope Department, University Museum, Oxford, England	(O)
The University Museum, Cambridge, England	(CAM)
The Rijks Museum van Natuurlijke Historie, Leiden, Netherlands	(L)
The Australian Museum, Sydney	(A)
M. Lhomme's Collection, Doutelle, Lôt, France	(ML)
M. Le Marchand's Collection, Paris	(LE)
Mr. Fernando Bourquin's Collection, Buenos Aires, Argentina	(FB)

In addition to the information received from the institutions and individuals listed above much other information, though largely negative in character, has been acquired from several other sources. Through Victoria H. Raica, Keeper, Muzeul de Istorie Naturală, Bucharest, Rumania, I have received word that the collection of Prince Aristide Caradja is in that Institution. The Caradja collection contains between 200 and 300 types but without confirmation and verification I cannot list the species. In a letter to me Prince Caradja stated that the types received by him from Meyrick are those listed in the several papers dealing with the Chinese material.

According to the Curator, Sarawak Museum, there are no Meyrick types in that collection. I failed to find the types of the species described in the Sarawak Museum Journal in the Meyrick collection and cannot give any information regarding their location.

Dr. W. R. B. Oliver, Director, Canterbury Museum, Christchurch, C.I., New Zealand, has advised me that there are no types in that Institution.

World War II has taken its toll also, as I was informed by Professor Dr. B. Klatt, Director, Hamburgisches Zoologisches Museum und Institut, Hamburg: "Zu Ihrer Anfrage vom 10 Febr. muss ich Ihnen leider mitteilen, dass unsere Lepidopteren-sammlung bei einem der Bombenangriffe im Jahre 1943 vernichtet wurde, so dass wir Ihnen von Seiten des Museums aus, zu unserem Bedauern nicht behilflich sein können." Certainly there were some Meyrick types there but the number, or the species are unknown.

In the Castle Museum, Norwich, England, there is at least one holotype (*Scoparia coprista*) but since the Pyralidoids are beyond the scope of this work further reference to this species will be omitted. I am indebted to E. A. Ellis, Esq., for the above information.

Dr. J. N. Mukherjee, Director, Indian Agricultural Research Institute, has advised me that there are no types either at New Delhi or in the "Indian Pusa Collection" although some species may be represented by paratypes or cotypes.

CATALOGUE OF MICROLEPIDOPTERA DESCRIBED  
BY EDWARD MEYRICK

Specific name	Generic name	Original reference and location of type specimen
<b>abacodes</b>	MELASINA	1908, <i>Proc. Zool. Soc. London</i> , p. 749.
